Introduction

- Wild Columbia River salmon populations are declining despite over a 100 years of supplementation and stream habitat restoration efforts
- A simplification through time of early life history behavior of salmon may have contributed to the decline
- Chinook salmon exhibit a variety of life history types, with behavior linked to rearing environment and migratory timing
- Chinook salmon rear throughout the tidal freshwater, estuarine, and marine regimes in the Columbia River estuary
- Expression of life history diversity was influenced by anthropogenic and natural pressures
- Life history diversity changes, i.e., estuarine rearing and growth, migration timing, and duration of migration, manifest in the estuarine regime (Figure 1)
- Estuarine rearing by juvenile chinook salmon plays an important role in the salmon life cycle
- Comparative evaluation of estuarine life history diversity captures the results of changes through the life cycle of chinook salmon

Methods

- Literature review of salmon life history and anthropogenic changes in the Columbia River Basin
- Collected published and unpublished data
- Reconstructed historic chinook salmon life history
- Analyzed the differences between historical and contemporary salmon life histories in the Columbia River estuary
- Summarized anthropogenic factors that contributed to changes in salmon life history diversity

Results

Contemporary Comparison

- Hatchery-reared chinook salmon displayed a relatively homogeneous size structure throughout the summer, indicating a lack of population diversity compared to historic runs (Figure 3).
- Timing of salmon through the estuary correlated to hatchery release dates
- Contemporary data lacked comparable estuarine growth measurements

Historical Reconstruction

- Historic estuarine sampling dated back to 1914 to 1916 by Rich (1920). Contemporary timing and relative abundance derived from Dawley et al. (1995) sampling at Jones Beach.

Figure 2. Historic and contemporary early life history types for one brood year of chinook salmon in the Columbia River estuary. Historic timing and relative abundance based on historic sampling throughout the lower estuary (Rich 1920). Contemporary timing and relative abundance derived from Dawley et al. (1995) sampling at Jones Beach.

Figure 3. Subyearling chinook salmon fork length range during three summer sampling periods (March to September).

Anthropogenic pressures on life history diversity:

- Harvest began in the early 1800s, intensified with the advent of canneries along the lower Columbia River, and continues today
- Fish passage limited by the Columbia River dams and migration structures during both the upriver migration of adults and the downstream migration of juveniles (Figure 4)
- Watershed alteration includes the loss of populations due to impasurable barriers, the degradation of spawning and rearing habitat, and the loss of estuarine habitat (Figure 5)
- Hatcheries supplemented populations beginning in the early 1980s and have failed to restore the natural populations and may contribute to the demise of wild salmon through competitive interactions

Conclusions

- The life history complexity of historic Columbia River basin salmon populations was evident in the numerous juvenile life history stages, sizes, and timing in the estuary
- A component of the historic wild salmon populations reared for a significant period in the estuary, indicating the importance of the estuarine regime in the life cycle of salmon
- Life history diversity of chinook salmon was reduced during the 20th century
- Contemporary use of the Columbia River estuary by wild juvenile salmon was relatively unstudied
- Documentation of contemporary wild salmon life history diversity was limited
- Hatchery-reared salmon dominated our characterization of salmon life history
- The Columbia River estuary and basin formerly sustained salmon with diverse life histories prior to natural and anthropogenic changes (in the basin)
